Case Description: Completed / Regular / X-ray / Specific region(s)

Case History:

Routine OFA testing for breeding

Case Report:

559266 KW/tr

Four digitalized radiographic images containing projections of the pelvis and elbows were submitted for evaluation. The radiographs are dated 4/8/22.

Radiographic Findings:

Both femoral heads are located in their respective acetabula with greater than 50% of the left femoral head and approximately 50% of the right femoral head located medial to the dorsal acetabular rims.

Both femoral heads are congruous with the acetabula and slight widening of the medial aspect of the right coxofemoral joint.

No osteophyte formation is present on the femoral necks or acetabula.

Alignment of the patellae with the femurs is normal.

Muscle volume in both hind legs within normal limits.

The anconeal process of both ulnas and proximocranial aspect of both radii are smooth and no evidence of osteophyte formation.

No sclerosis is associated with the ulnar notches.

Both medial coronoid processes are smooth in contour and a fragment associated with the medial coronoid processes is not identified.

Radiographic Diagnosis: Normal pelvis and elbows.

Comments: Radiographic changes to suggest elbow or hip dysplasia are not present. Based on the OFA scheme evaluating hips, the hips were rated as good in conformation. Radiographs obtained at two years of age will need to be evaluated to completely exclude elbow and hip dysplasia and to establish a final rating on the coxofemoral joints.
